# Why Study Nanomechanics by AFM?

- Influence of nanoscale mechanical properties on macroscale behavior
  - Distribution of domains in heterogeneous material
  - Mechanical properties of those domains
- Bulk methods require large amount of material
- Nanoscale methods allow access to components in-situ
  - Small amount of material
  - Domains confined within matrix or adjacent to filler

*Epitaxial lamellae at barrier-tie interface: heat sealed food packaging*

# AFM Imaging Technology

- Mapping topography -> More information
  - Contact mode & force spectroscopy (1986)
  - TappingMode & phase imaging (1992)
  - Force-Volume Mapping (~1992)
  - Contact Resonance (AFAM, UAFM~1996)
  - HarmoniX (2008)
  - PeakForce Tapping/QNM (2010)
    - PeakForce TUNA (2011)
    - PeakForce KPFM (2012)
    - PeakForce sMIM (2015)
    - PeakForce SECM (2016)
  - Fast Force Volume (2014)
  - FFV – Nanomechanics/CR (2016)
  - FFV – Nanoelectrical (2018)
  - AFM-nDMA

*More to come ...*

# Nanomechanical Measurement Techniques with AFM

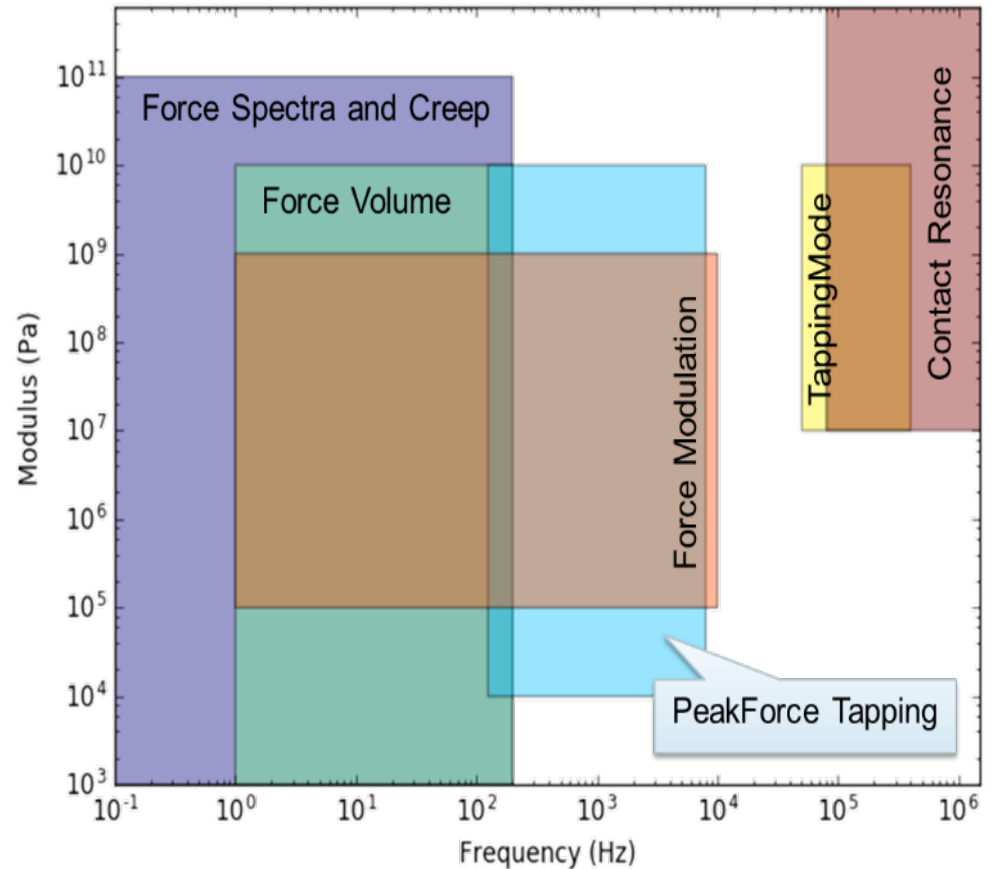

- **Force Spectroscopy** (Elastic Modulus)
- **Phase Imaging** (Convolution of elastic and viscoelastic properties)
- **Contact Resonance** (Viscoelastic Properties at high frequency)
- **PeakForce QNM** (Elastic Modulus)
- **AFM-nDMA** (viscoelastic moduli)

# Different AFM modes & cantilevers cover wide range of modulus and measurement frequency

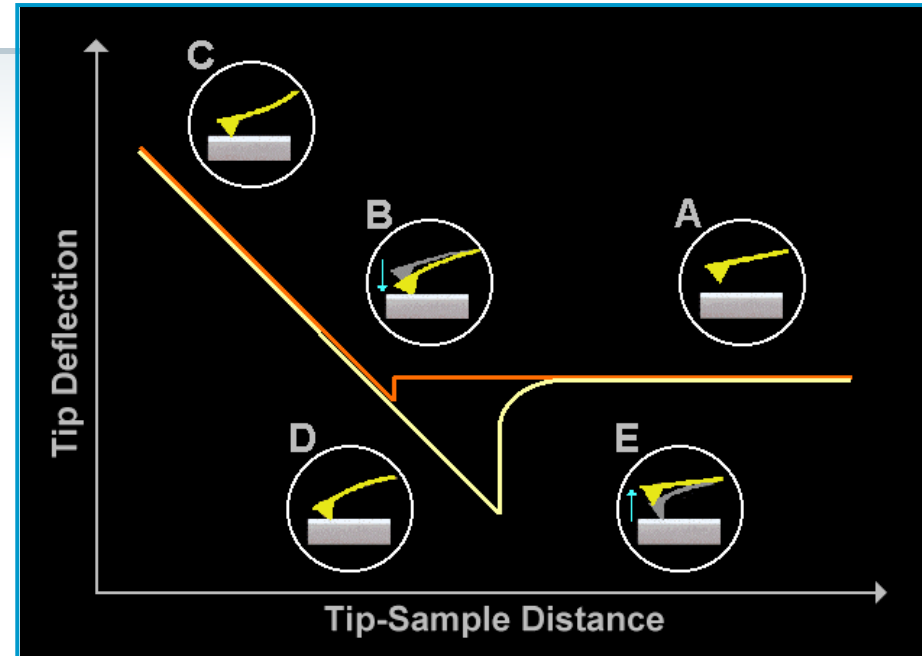

- At first glance, covers range of frequencies and moduli
- For sure AFM offers attractive spatial resolution
- Repeatable measurements possible with good system calibration

# Force Spectroscopy for Nanomechanical Measurements

- Force-Distance curves collected and fit with models to measure
  - Elasticity/Stiffness
  - Adhesion
  - Attraction

Modified from Cox and Erler. *Dis. Model. Mech.* (2011) 4: 165-178.

# Interpreting Force Curves

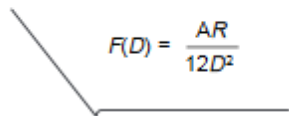

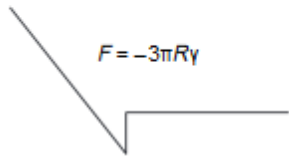

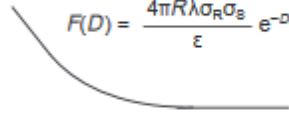

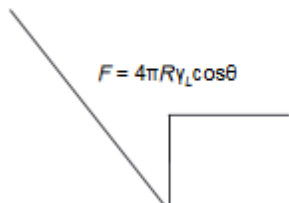

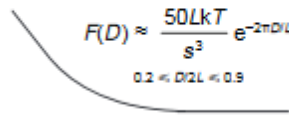

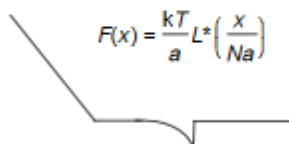

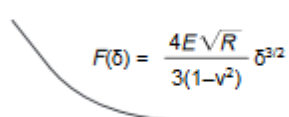

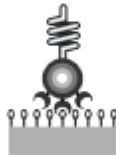

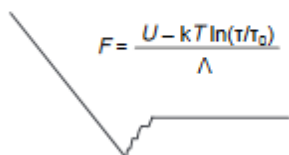

## Measures

- attractive,
- repulsive, and
- adhesive forces between tip and sample

## Applications

- investigating fundamental force interactions
- nano-scale adhesive and elastic response
- binding forces
- colloidal studies
- chemical sensing

| Approach  |   | Retraction  |   |
|---|---|---|---|
| <b>a van der Waals</b><br><br>$F(D) = \frac{AR}{12D^2}$  |    | <b>e Adhesion</b><br><br>$F = -3\pi R\gamma$   |    |

# Nanomechanical Properties of Tissues

## Mammary Gland

- Role of forces in disease states (eg. breast cancer).
- Mammary gland becomes increasingly stiffer with tumor progression.
- Force curves show lymph node stiffness > mammary tissue stiffness.

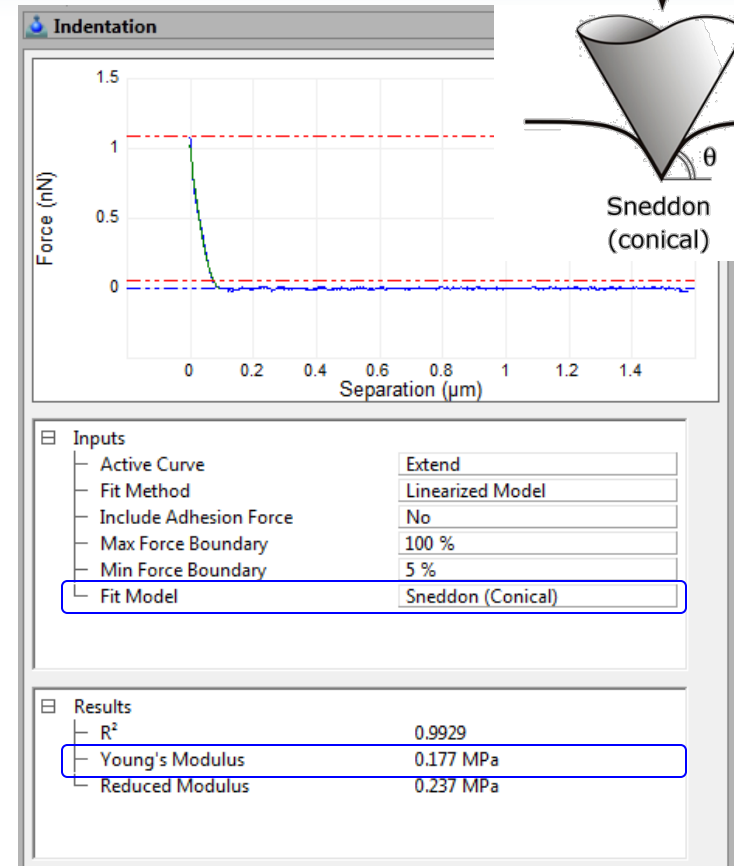

# Example: Indentation Analysis

## -Choosing an indentation model

Force curve taken on a live HEC1A cell with a 5µm radius colloid probe cantilever

Force curve taken on a live HeLa cell with an unmodified MLCT probe

# Force Volume Imaging: Principle

- A force-distance curve in each pixel of the image
- The force-distance curve is 'triggered': the Z movement stops when a user-defined force (trigger) is reached. The Z position at this force is used to construct the Height image
- All force distance curves are used to create 'force slice' images.

# Force mapping in mechanobiology – conventional approach

- 2-Dimensional array of force curves conducted over a defined scan area.
- Disassembly of actin filaments after treatment of living 3T3 fibroblast cells with the drug Cytochalasin B.
- Slow acquisition speeds and low resolution have hindered wide adoption.

Radmacher et al. (2000) *Biophys. J.*, vol 78: 520-35.

# Widest Range – High Speed Quantitative Data with *FAST*ForceVolume

- Highest speed linear ramping, to 300Hz
- All the data: pixel resolution up to 256x256x2048 or 956x956x256
- Real-time analysis: Instant property channels incl adhesion and modulus
- Force control with <math>< 50\text{pN}</math> low force trigger
- Study time dependence – closes gap between traditional slow ramps and PeakForce Tapping

# Phase Imaging for mechanical contrast

Polyurethane material

Y.Tang, U.of Toronto

# Phase Imaging: Component maps, more complex

- Rubber Material (EPDM+iPP+CB), 5um scan

Height

Phase

CB particles

EPDM areas  
with  
different  
cross-  
linking  
density

PP-  
matrix

Phase imaging shows high sensitivity, allowing one to differentiate different components

# Phase contrast highly variable

- Polypropylene-Rubber blend, 5um scan

Limitation: Phase images strongly depend on parameter settings (drive amplitude & amplitude setpoint) and can even reverse contrast

# PeakForce Technology

*Controls and measures force as feedback*

*Resembles a typical force curve...*

## PeakForce Mode:

- Probe modulated at small amplitudes at low frequency (1-2kHz).
- Feedback signal is peak force between tip and sample.
- Direct control of imaging forces with ultra-low setpoints (<100pN).
- Images acquired at typical scan rates (1000's force curves/sec).

- When the linear motion is replaced with a sinusoidal motion, we can ramp much faster: for example 2kHz – *this is unique*
- Instead of 'force trigger', we will use true feedback on the maximum or 'peak force' = much *better force control*

- Result:
  - Standard imaging speed
  - Full force mapping
  - Extreme good force control (down to < 20 pN)

# PeakForce QNM

Topography and material property channels collected simultaneously in a single scan

Height

Modulus

Deformation

Adhesion

Dissipation

# Quantifying PeakForce QNM data

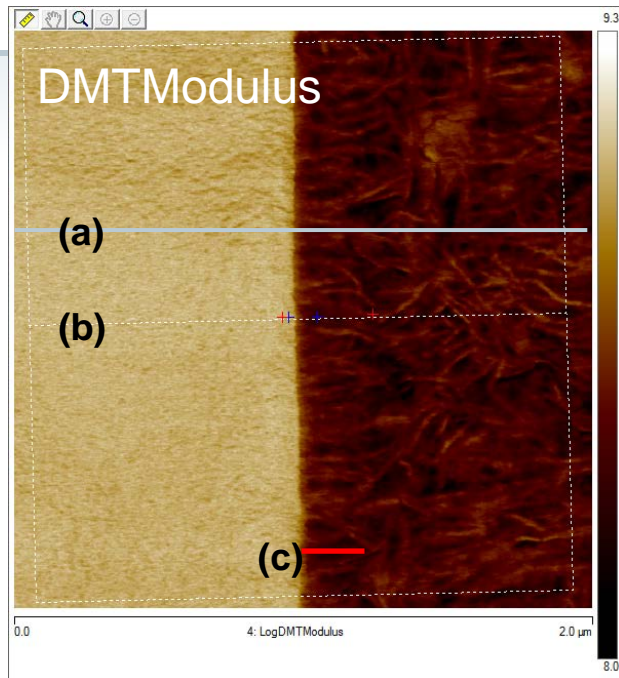

Height, Modulus & Adhesion maps of Polydiethylsiloxane (PDES) on Si showing the 3 different materials with high resolution and in normal imaging time (9 min for 512x512 image)

3-compound polymer: hard matrix with rubbery inclusions & semi-crystalline phases. The modulus image & histogram show the 3 materials with high resolution.

# Polymer composites

## Heat-sealed bag

### Barrier layer

Nylon

Strength & gas impermeability

### Tie layer

ULDPE

Preserves layer adhesion

### Sealant layer

Metallocene PE/LDPE blend

Adheres to itself when heated

**Barrier and Tie layers are incompatible, so we expect a relatively abrupt interphase.**

- Single scan line has a clear step in modulus over a distance of  $\sim 75\text{nm}$ .
- Lamella do not cross the interface, but grow epitaxially from the Barrier layer  $\sim 250\text{nm}$  into the Tie layer.

# Polymer composites

## Heat-sealed bag

### Barrier layer

Nylon  
Strength & gas impermeability

### Tie layer

ULDPE  
Preserves layer adhesion

### Sealant layer

Metallocene PE/LDPE blend  
Adheres to itself when heated

**Tie and Sealant layers are more compatible, so we expect a wider interphase.**

- Single scan line: the variation in modulus is dominated by individual lamella.
- Collectively: modulus varies over a much wider range  $\sim 250\text{nm}$  to  $\sim 1\mu\text{m}$ .
- Lamella from Tie layer act as nucleation sites or penetrate into the Sealant layer resulting in a more ordered region up to  $\sim 1\mu\text{m}$  from the interface.

# Analyzing Force Curves: FV & PFT

*From Deflection and Z to modulus*

1. Eliminate time
2. Apply 'Deflection sensitivity'
3. Apply 'Z sensitivity'

4. Calculate indentation
5. Apply 'Spring constant'
6. Fit data with contact mechanics model

# Force Volume Error Analysis

- Potential sources of error include:
  - Tip radius ( $R$ ) ~ 15%
  - Spring constant ( $K_c$ ) ~ 6-16%
  - Deflection sensitivity ( $sd$ ) ~ 5%
  - Deflection voltage ( $V$ ) ~ 1%
  - Z position ~ 1%

- Conclusion
  - Low modulus limit is dominated by error in  $R$  and  $K_c$
  - High modulus limit dominated by error in  $Z$  and Deflection Sensitivity

Application Note #149

## Improving the Accuracy of Nanomechanical Measurements with Force-Curve-Based AFM Techniques

The structure and mechanical properties of sub-micron features in materials are of particular interest due to their influence on macroscopic material performance and function. Atomic force microscopy has the high resolution and force control to directly probe the mechanical properties of a wide range of these materials. This application note discusses the development and implementation of several new features that improve the flexibility, accuracy, and productivity of atomic force microscopes (AFMs) in measuring such important material properties as modulus and adhesion.

Introduction

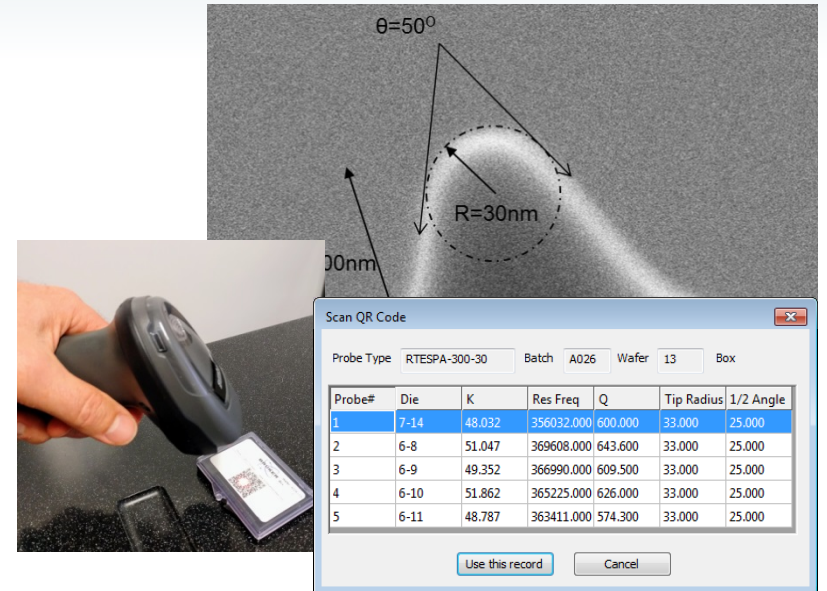

for calibration of multiple parameters associated with the atomic force microscope (AFM) cantilever.

Addressing the speed problem, FASTForce Volume™ has been introduced on Bruker Dimension Icon®, Dimension FastScan®, BioScope Resolve®, and MultiMode® AFM systems to improve force spectroscopy measurements. Building on the conventional force curves, FASTForce Volume can make the same measurement but at much higher ramp rates, resulting in a tenfold decrease in acquisition time. For example, a force curve map of 128x128 pixels previously took 30 minutes, but now only takes about 3 minutes. The same maps of modulus, adhesion, and height in real time are still performed, but

# How did we improve the accuracy of Force Volume & PeakForce Tapping?

- New probes for materials
  - LDV calibrated spring constants
  - Controlled tip radius = 33nm
  - Selection of spring constants to cover range of moduli
    - 0.25, 5, 40, 200 N/m
- New probes for cellular work
  - Calibrated spring constant <math>< 0.1\text{N/m}</math>
  - Controlled tip radius = 65nm
  - Tip Height – 17um
- Guided calibration software for deflection sensitivity
- Better contact modeling

# PeakForce QNM – Guided calibration

## Touch Calibration

- High accuracy, guided calibration of key parameters for force spectroscopy and PF-QNM
  - Calibrates Deflection Sensitivity, Spring Constant, QNM Sync Distance, PFT Amplitude Sens
- **No-Touch calibration also available**
- Spring constant calibration by Thermal Tune or Sader Method

The screenshot displays the 'Touch Calibration' software interface, which is organized into several sections:

- Thermal Tune:** A section for calculating initial parameters.
- Locate Sample and Engage:** Includes instructions to confirm a hard sample and find an appropriate location. It features controls for 'Move XY Stage' (Speed 100%), 'Move Scan Head' (Speed 3%), and buttons for 'Engage' and 'Withdraw'.
- Deflection Sensitivity:** A section for calibrating Deflection Sensitivity and Spring Constant. It includes a 'Use Ramp' section with 'More Settings' and a 'Ramp' button. The 'Current Values' section shows: Deflection Sensitivity: 103.07 nm/V, Spring Constant: 8.1948 N/m. The 'Calculated Values' section shows: Deflection Sensitivity: 103.07 +/- 0.48 nm/V, Spring Constant: 8.1948 N/m. An 'Update Current Values' button is present. To the right is a graph of Deflection Error (nm) vs Height Sensor (nm).
- Calibrate PeakForce QNM:** A section for calibrating Sync Distance QNM and PFT Amplitude Sensitivity for each desired frequency. The 'PFT Frequency' is set to 2 kHz. It includes a 'More Settings' dropdown and a 'Calibrate' button. The 'Deflection Sensitivity Convergence Comparison' section shows: Def Sens Target: 103.07 nm/V, Defl Sens from Cur PFT Ampl Sens: 103.87 +/- 1.00 nm/V. The 'Current Values' section shows: Sync Distance QNM: 29.06%, PFT Amplitude Sens.: 682.50 nm/V. The 'Calculated Values' section shows: Sync Distance QNM: 29.25% +/- 0.01%, PFT Amplitude Sens.: 677.24 nm/V. An 'Update and Verify Current Values' button is present. To the right is a graph of Force (mN) vs Z (nm).
- Finish:** A section with two buttons: 'Return and Save Updated Values' and 'Return and Cancel Updated Values'.
- Status:** A 'Status: Engaged' indicator.

# Accuracy of PF-QNM (vs. DMA)

## Ternary polymer blend

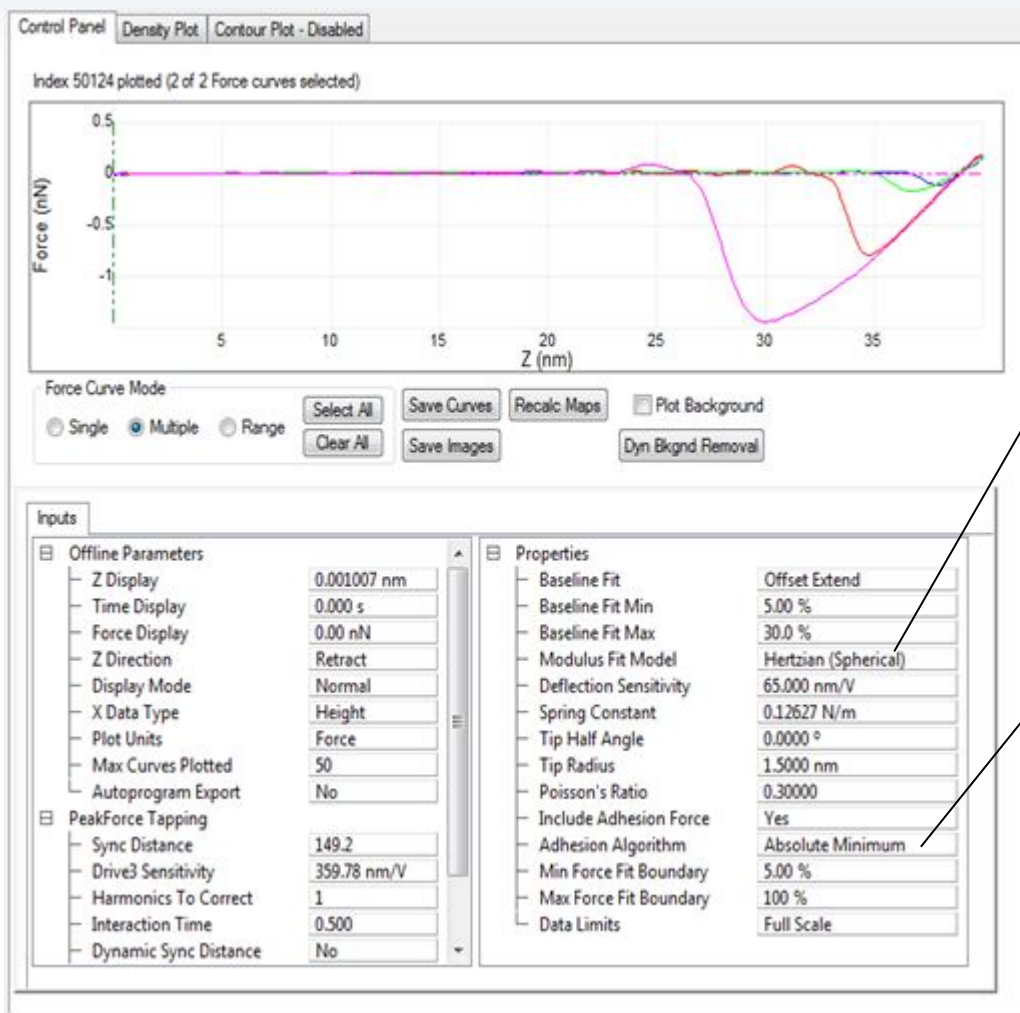

|           | PP   | PE   | PS   | PE:PP | PS:PP |
|-----------|------|------|------|-------|-------|
| DMA       | 2.19 | 1.95 | 2.92 | 0.89  | 1.33  |

# Force spectroscopy maps can be collected using PeakForce Capture during PeakForce QNM imaging, or FastForce Volume

*Recalculation of saved data with different models for modulus and adhesion*

PeakForce Capture provides the force curve at each pixel up to 256x256

- Hertzian (Spherical)
- Hertzian (Spherical)
- Sneddon (Conical)
- Cone Sphere
- JKR Full (Spherical)**
- JKR 2 Point
- JKR 2 Point - Stiffness

*Modulus models*

- Absolute Minimum**
- Threshold Crossing
- Positive Slope
- Absolute Minimum

*Adhesion models*

Individual force curves can be accessed and analyzed at each pixel.

Modulus, Adhesion, and Stiffness maps can be recreated using different models or acquisition parameters, such as spring constant or deflection sensitivity

# Hydrogel in fluid - FastForce Volume map 20um area

Each image of force data can be saved and analyzed individually

Often use Live Cell pre-calibrated probes for this measurement on Hydrogels

Sample courtesy Fangzhou Xia, MIT

# Modulus map – 20um area

Using Sneddon model for modulus calculation

Mean value = 7.4kPa, Std Dev 0.541kPa

# Ramp & Force Volume Expansion

*Ramp&Hold based measurements*

- **Relaxation: best for very soft samples with long relaxation times**
  - Hold Force or Z sensor
  - Measure Z sensor or Force
  - Fit hold data to calc. viscoelastic props
- **Force Modulation: best for moderate stiffness samples**
  - Add modulation: single frequency or sweep during hold
  - Measure amplitude and phase at frequencies far below contact resonance
  - Calculate storage & loss modulus from hold data
- **Contact Resonance: best for stiff samples**
  - Add modulation: sweep frequency while holding force
    - Range chosen to cover contact resonance
  - Fit CR peak to find  $f$ ,  $Q$
  - Calc. storage & loss modulus from  $f$ ,  $Q$

# Ramp&Hold Z or Force Stress or Strain Relaxation

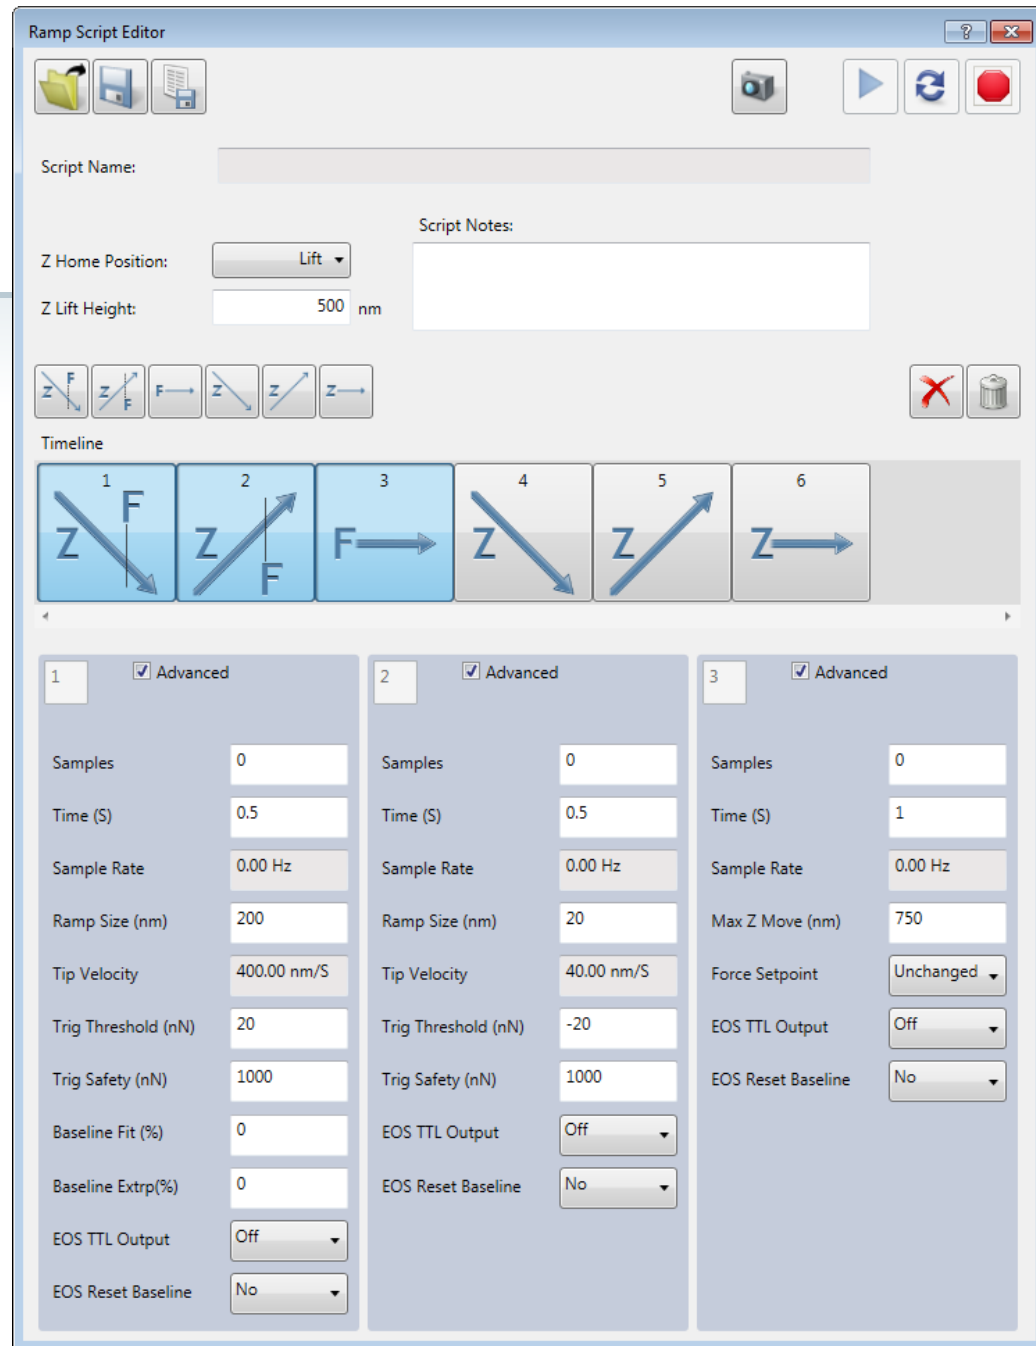

- Hold Z, hold trigger force, or hold user defined force
- Integrated with Force Volume
- Easy: similar to ramp mode
  - Typical ramp time ~0.1-10sec
  - Typical Hold time ~1-5000sec.
  - User definable sample rates
- For Ramp&Hold > a few sec, the plot is updated during acquisition and can be cancelled
- Offline analysis

# RampScript Editor

- Multi-segment types and control in a single script.
- Force Ramps and Frequency Sweeps.

The screenshot shows the Ramp Script Editor interface. At the top, there are icons for file operations and playback controls. Below that, the 'Script Name' field is empty. The 'Z Home Position' is set to 'Lift' and the 'Z Lift Height' is 500 nm. A 'Script Notes' text area is present. A row of icons represents different movement types: Z down with F, Z up with F, F right, Z down, Z up, and Z right. Below these is a 'Timeline' showing six segments. Segment 1 is highlighted and shows a Z down ramp with a force ramp (F) starting at the end. Segment 2 shows a Z up ramp with a force ramp (F) starting at the beginning. Segment 3 shows a force ramp (F) moving right. Segments 4, 5, and 6 show Z down, Z up, and Z right movements respectively. Below the timeline are three configuration panels for segments 1, 2, and 3, each with a 'Advanced' checkbox checked. Each panel contains various parameters such as Samples, Time (S), Sample Rate, Ramp Size (nm), Tip Velocity, Trig Threshold (nN), Trig Safety (nN), Baseline Fit (%), Baseline Extrp(%), EOS TTL Output, and EOS Reset Baseline.

| Segment | Advanced | Samples | Time (S) | Sample Rate | Ramp Size (nm) | Tip Velocity | Trig Threshold (nN) | Trig Safety (nN) | Baseline Fit (%) | Baseline Extrp(%) | EOS TTL Output | EOS Reset Baseline |

# Viscoelastic Properties of Cells

## *Studying Time-Dependent Mechanical Properties*

- To fully understand cell mechanics need to consider viscoelastic properties (time-dependent)
- Ramp Scripting on ICON and Resolve
  - Easy to use software interface for designing customized, advanced force measurement studies
  - Scripts can be conducted at single point positions or as an array for mapping viscoelastic properties

# Ramp Scripting for Mechanobiology

*Viscoelastic Creep Response of Living Fibroblast Cells*

MIROView was used to target the:  
(1) cell nucleus, (2) cell extension, (3) petri dish.  
MLCT-Bio-DC probes ( $k \sim 0.011 \text{N/m}$ ).

- Advantages of Ramp Scripting on Icon:
  - Fast feedback (z movement < 10msec)
  - High stability (holds over several seconds)
  - Most sensitive force control ( $\sim 10 \text{pN}$ )
  - Per segment TTL for synchronization

# New Force Hold with Frequency Sweep for Dynamic Mechanical Analysis

- New integrated frequency sweep during hold enables dynamic mechanical analysis (DMA).
- DMA provides frequency domain response spectrum. Amplitude and phase, can be converted to storage and loss modulus as function of frequency.

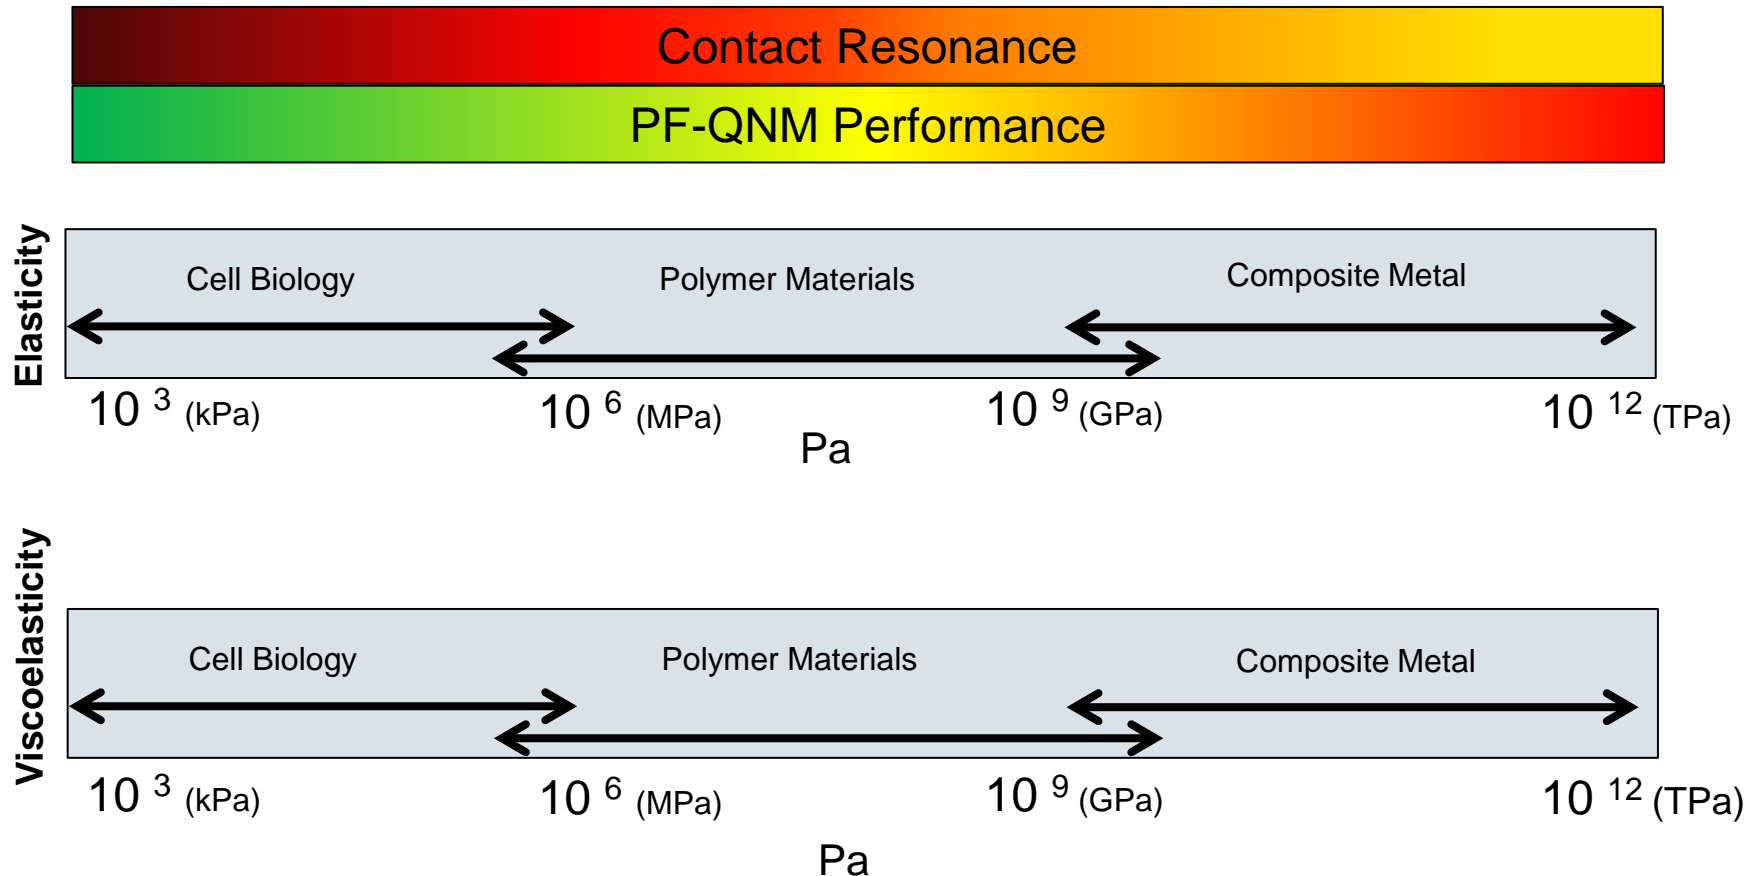

# Elasticity and Viscoelasticity Characterization

Accurate Measurements of Materials 1kPa to 300+ GPa

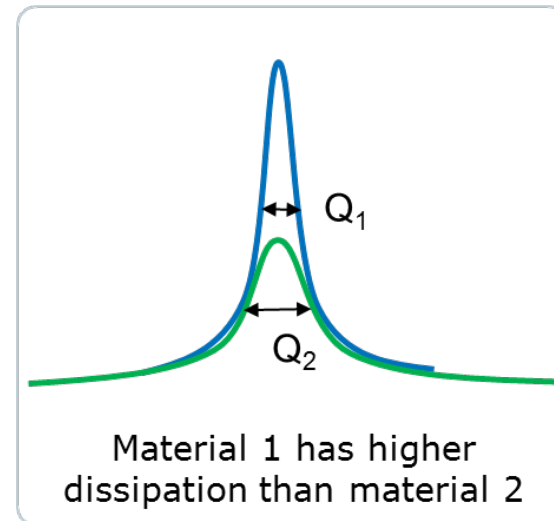

## Complete Solution for Nanomechanical Characterization

# Contact Resonance Mode Principle

- Developed in the 1990s
- Tip is in contact with the sample
- Sample is placed on an actuator which oscillates the sample at fixed amplitude over a frequency range
- Cantilever (contact) resonance spectra are measured in each pixel and provide storage & loss modulus at a discrete (high) frequency
  - Dissipation is proportional to Quality factor  $Q$
  - Stiffness is proportional to frequency

# Contact Resonance Mapping Principle

- In every pixel, a standard force curve + contact resonance spectrum is acquired
  - Approach
  - Hold Force and sweep frequency
  - Retract
- Compared to contact mode: **More repeatable & longer tip lifetime** (lateral force on tip is minimized)
- Allows measurement of **Adhesion** force for each pixel = better contact mechanics modeling
- Real-time maps of both raw data and mechanical properties ( $E'$ ,  $E''$ , loss tan)

# Contact resonance for hard materials

- Al & Cr film on Si, 10um scan

- Principle:

- Tip is in contact with the sample
- Using a transducer, the sample is excited mechanically at & around contact resonance frequency
- Measure  $f_{CR}$  &  $Q_{CR}$  at the contact resonance
- $f_{CR}$  &  $Q_{CR}$  can be translated into [storage & loss modulus](#)

- Good sensitivity for stiff samples (10-300GPa)

# Contact Resonance Mapping Probes & Samples

- 3 probe types
  - Diamond coated
  - Various spring constant cover modulus range from 1 GPa to 300+ Gpa
  - Note: During development, our engineering team used 6 probes to collect over 2.7 million CR spectra and lasted 257 hours of CR operation
- 7 reference samples
  - HOPG, Mica, Fused Silica, Al (50nm film), Si, Cr (50nm film), and Sapphire

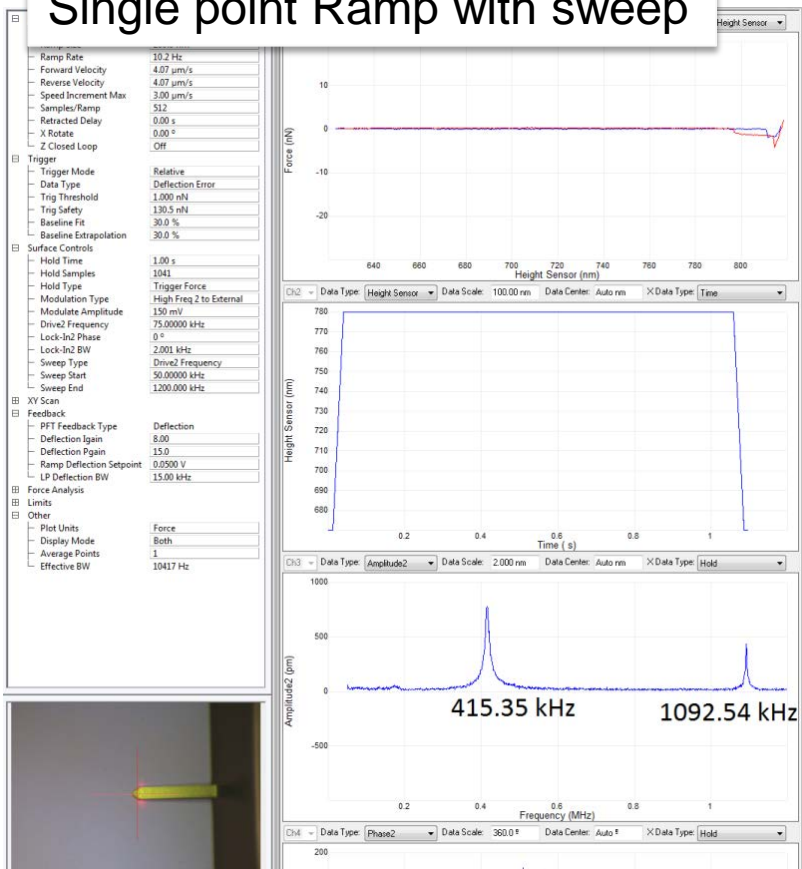

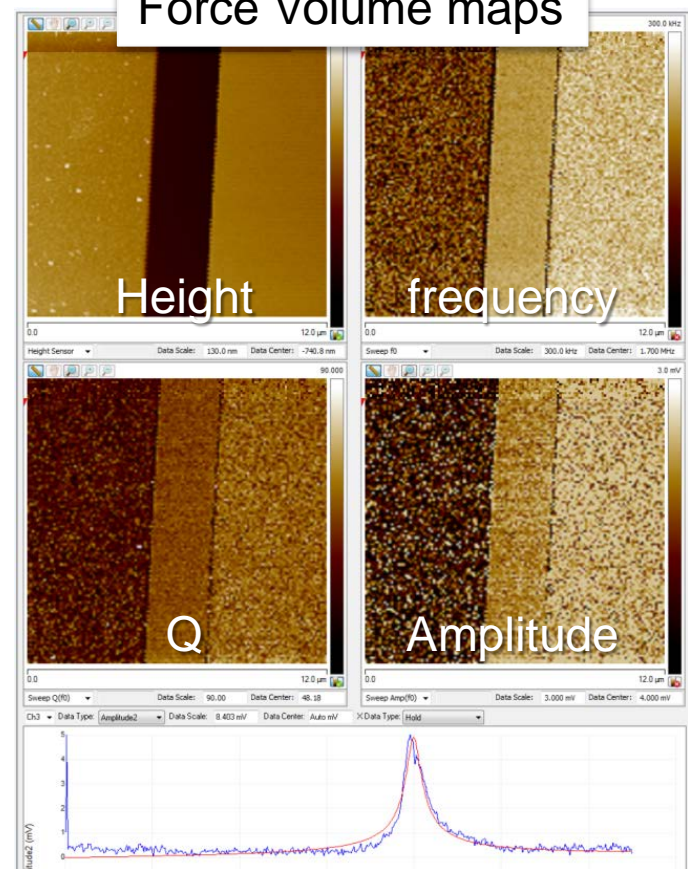

# Contact Resonance Mapping 'Raw data' Example

## Single point Ramp with sweep

## Force Volume maps

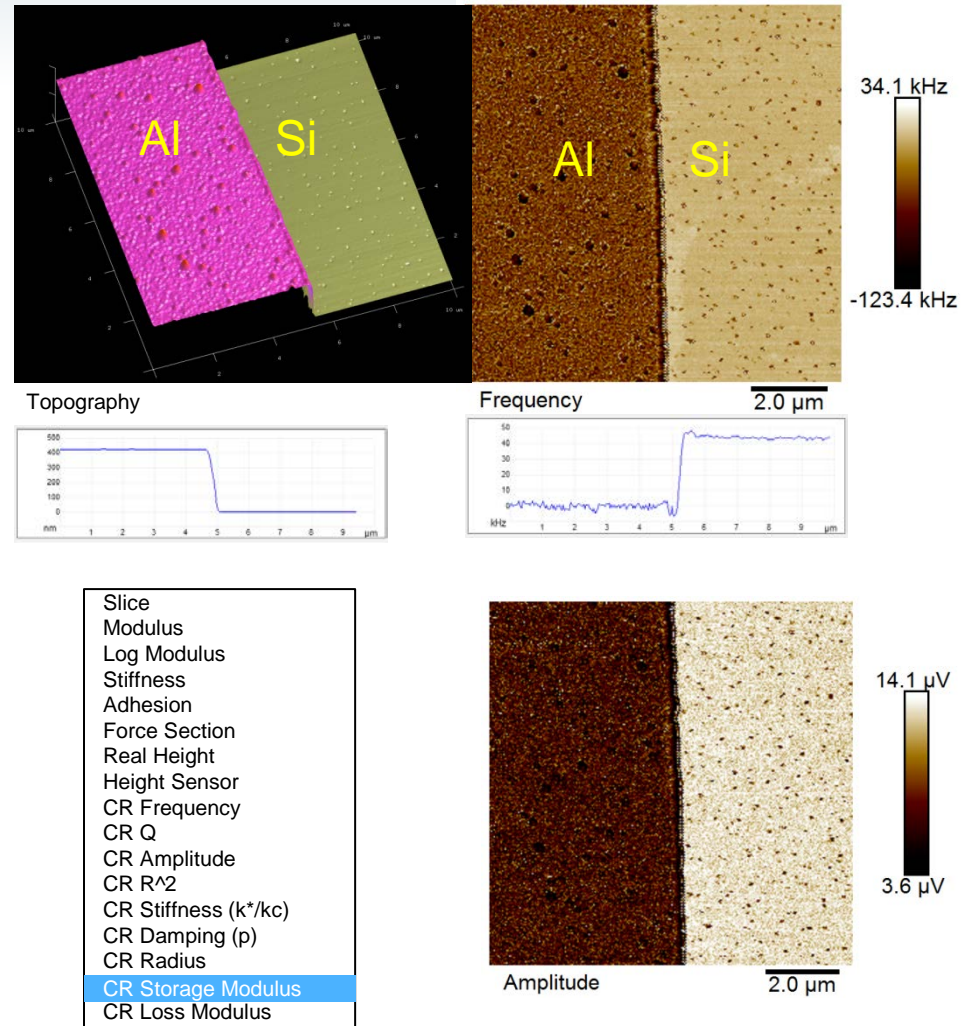

In Force Volume: Ramp and hold trigger force, then sweep at each pixel.

# Contact Resonance Mapping

## Sample: Al film on Si

- 10x10  $\mu\text{m}$  scan
- Large amount of data:
  - Every force curve includes 4 channels
  - 256x256 pixels (2048 spectra points)
  - Maximum 956x956 pixels (256 spectra points)
- More than 15 data types can be selected:
  - Frequency, Amplitude & Q
  - Loss Modulus & Storage Modulus
  - Tan delta
  - Adhesion
  - ..

# Contact Resonance Mapping Loss Modulus & Loss Tangent

- Loss modulus can be calculated from the Q of the CR peak
- Research community lacks consensus about the best way to do this, so we implemented three algorithms
  - YHT 2008 and Rabe 2006 are very similar and both require the reference sample to have a known loss modulus
  - PKAS 2016 does not require a reference sample with known loss modulus

| Inputs Contact Resonance |                                    |

$$\tan \delta = \frac{E''}{E'}$$

PS-PMMA topography with false coloring by loss modulus.

# What about frequency dependence? AFM-nDMA

- $E'$  and  $E''$  (or  $\tan \delta = E''/E'$ ) vary with frequency & temperature
  - $E'$  of amorphous polymers increase with loading rate or decrease with temperature
  - Variation can be quite significant!
- Rheologists need measurements at multiple frequencies and temperatures for a complete analysis

Bulk dynamic modulus of Isotactic polypropylene (Read, B.E 1989)

# Imaging focused modes - not suited for quantifying viscoelasticity

- Probing sample impulsively
  - Plunge-in and rip-out in each cycle, make-and-break contact
  - Not a linear measurement
  - Since it's not linear, the nominal frequency is not the only frequency
  - Cannot really quantify frequency dependence
- Tapping based methods introduce added constraints
  - Frequencies fixed and 100,000x too high
  - Challenge in quantifying load and adhesion

# Start with time dependence

## Basic idea of AFM mode for rheology

- Approach: Preload the sample at known force
- In contact: Modulate at well-defined, rheological freq, low amp
  - Low amplitude provides small perturbation in force: linear regime
  - Cover 0.1Hz to 300Hz: single frequency or spectrum
- Retract: fit with contact mechanics model that includes adhesion (e.g. JKR) to obtain contact radius ( $a_c$ )
  - Need contact radius to extract moduli ( $E'$ ,  $E''$ ) from raw data

*T. Igarashi, S. Fujinami, T. Nishi, N. Asao, and K. Nakajima, Macromolecules (2013)*

# AFM-nDMA theory

- Need to extract amplitude ratio ( $D_1/Z_1$ ) and phase shift ( $\phi - \psi$ ) and do a little complex algebra to get

*stiffness = force/deformation*

- $S^* = S' + iS'' = K_c D_1 e^{i\phi} / [Z_1 e^{i\psi} - D_1 e^{i\phi}]$

- $S' = \frac{K_c D_1}{Z_1} \frac{\cos(\phi - \psi) - D_1/Z_1}{(\cos(\phi - \psi) - D_1/Z_1)^2 + (\sin(\phi - \psi))^2}$

*Elastic component, in phase*

- $S'' = \frac{K_c D_1}{Z_1} \frac{\sin(\phi - \psi)}{(\cos(\phi - \psi) - D_1/Z_1)^2 + (\sin(\phi - \psi))^2}$

*Viscous component, out of phase*

- Loss tangent is then:  $\tan \delta = S''/S' = \frac{\sin(\phi - \psi)}{\cos(\phi - \psi) - (D_1/Z_1)}$

# Two modes quantify viscoelasticity

$E'$ ,  $E''$ ,  $\tan \delta$  at bulk DMA frequencies

- Mapping with Fast Force Volume
  - Simple, single modulation segment embedded in force curve

- Spectroscopy with RampScripting
  - measurements at multiple frequencies at a single point

# How are these spectra collected?

- An AFM-nDMA “RampScript” has segments that allow for control of preload, relaxation, modulation, and calculation of contact radius
- Low frequency segments use raw deflection for better filtering, while higher frequencies use lock-in based demodulation

# Managing changes in contact radius

Moduli  $E'$ ,  $E''$ , we also need a contact mechanics model like JKR to estimate contact radius ( $a_c$ )

$$E' = \frac{S'}{2a_c}; E'' = \frac{S''}{2a_c}$$

Reference segments correct evolution of contact radius over time

Measure  $S'(f_{ref})$  and assume  $E'(f_{ref})$  is constant during script

- To get moduli  $E'$ ,  $E''$ , we also need a contact mechanics model like JKR to estimate contact radius ( $a_c$ )
  - $E' = \frac{S'}{2a_c}; E'' = \frac{S''}{2a_c}$
- Reference segments correct evolution of contact radius over time
  - Measure  $S'(f_{ref})$  and assume  $E'(f_{ref})$  is constant during script

Loss Tangent

# What is AFM-nDMA – Hardware

- nDMA heater
  - Ramps and stabilizes 5x faster than standard heater-cooler
  - RT-250C, 0.1Hz-300Hz
- High frequency sample actuator
  - For 300Hz to 20kHz range at room temp
  - Produces total range of 0.1Hz to 20kHz
- Precalibrated probes solution
  - 2 end radii – 30nm and 125nm
  - 3 spring constants ~ 0.4, 5, 40N/m
  - QR reader for probe parameter reading
- Test & training samples
  - Validation (PDMS, FEP) and imaging (PPE, PC-ABS)

# Setting up AFM-nDMA spectroscopy

## Efficient generation of scripts

- Quick set up with DMA focus
  - Frequencies, preload, modulation amplitude
- Advanced parameters if wanted
  - Log vs linear frequency distribution
  - Frequency shuffle avoids artifacts
  - Modify reference segments
  - Change length of relaxation segment
  - Adjust any ramp parameter
- Or edit segment-by-segment in general ramp scripting interface
  - Maximum flexibility

# Addressing the smallest nanoscale domains with the highest AFM resolution on polymers

- PeakForce QNM achieves the highest resolution – allows targeting the smallest domains
- MiroView integrates AFM-nDMA with PeakForce QNM – use same probe, allows full automation
- Use AFM-nDMA maps for added quantitative information and to distinguish multiple phases
- Use AFM-nDMA frequency spectra for most complete information at targeted points

# Can a nanoscale measurement tie directly to bulk DMA?

- Nanoscale AFM-nDMA results show excellent agreement with
  - micrometer scale Hysitron Nanoindenter
  - millimeter scale Bulk DMA
- Consistent results across labs and operators (no reference samples)
- Directly cover bulk frequencies and extend to 20kHz with external actuator

# Time Temperature Superposition

- Collecting frequency spectra at several temperatures enables a more complete analysis
- TTS principle: near glass transition, raised temperature is equivalent to lowered frequency and vice versa
- Master curve: single curve resulting from shifting data measured at different temperatures
- Shift factors: can be parameterized via either WLF or Arrhenius model.
  - Arrhenius equation gives activation energy from temperature dependence of a rate – energy needed to kick off a mechanical relaxation process

Activation energy analysis for a polymer  
Arrhenius:  $\ln(aT) = -E_a/R (1/T - 1/T_0)$

# Summary

## *Recent Development in Nanomechanical Measurements by AFM*

- Force-based and Nanomechanical Techniques:
  - Force Spectroscopy
  - FastForce Volume
  - Peakforce Tapping/PeakForce QNM
  - Ramp Scripting and Ramp and Hold
  - AFM-nDMA (released Nov 2018)
  - Contact Resonance based on FastForce Volume
  - PeakForce QNM-High Accuracy (PFQNM-HA)
  - MIROView
  - Probes
